A descent datum for a morphism of commutative rings $\phi : R \rightarrow S$ consists of:

- an S-module M
- ► an isomorphism (of $S \otimes_R S$ -modules), $\theta : p_0^*(M) \xrightarrow{\cong} p_1^*(M)$
- a commutative diagram which constitutes the cocycle condition:

 $p_{10}^{*}(M) \cong p_{02}^{*}(M)$ $p_{00}^{*}(\theta) \xrightarrow{p_{01}^{*}(\theta)} p_{11}^{*}(\theta) \cong p_{12}^{*}(M)$

Definition

For an R-module N, define Aut(N) : $CRng^{\setminus R} \to Group$ by $Aut(N)(S) = Aut_S(S \otimes_R N)$.

Theorem (Ibid.)

The set of twisted forms for N along $\phi : R \to S$ is in bijection with the first (non-abelian) cohomology of the cosimplical group $Aut(N)(R/S^{\bullet})$:

$$Aut(N)(S) \Longrightarrow Aut(N)(S \otimes_R S) \Longrightarrow Aut(N)(S \otimes_R S \otimes_R S) \cdots$$

We often call the above cohomology group the *descent* cohomology of N.

Descent Cohomology & Twisted Forms in Homotopy

> Jonathan Beardsley

Classical Descent Theory

Twisted Forms and Descent Cohomology

Homotopical Descent (à la Lurie)

Sketch Proof:

► The module p₀^{*}(N) = (N ⊗_R S) ⊗_S (S ⊗_R S) ≅ N ⊗_R S ⊗_R S supports a canonical descent datum given by twisting the S factors:

$$can: p_0^*(N\otimes_R S) \stackrel{\cong}{\to} p_1^*(N\otimes_R S).$$

 Any other descent datum φ gives an automorphism after inverting can,

$$can^{-1} \circ \phi : p_0^*(N \otimes_R S) \xrightarrow{\cong} p_0^*(N \otimes_R S).$$

 A suitable automorphism can be composed with the canonical descent datum to obtain a new descent datum. Descent Cohomology & Twisted Forms in Homotopy

- Similarly to the discrete case, we now want to determine the space of twisted forms using some kind of "cohomology."
- However, since there is a space of twisted forms, we need a Bousfield-Kan spectral sequence to get at this information!
- ► For a given *R*-module *N*, the cosimplicial space of interest is:

$$Aut(N)(S) \rightrightarrows Aut(N)(S \otimes_R S) \rightrightarrows Aut(N)(S \otimes_R S \otimes_R S)$$

 Specifically we want to understand the data in cohomological degree one (i.e. the homotopical analogue of H¹). Descent Cohomology & Twisted Forms in Homotopy

> Jonathan Beardsley

Classical Descent Theory

Twisted Forms and Descent Cohomology

Homotopical Descent (à la Lurie)

Theorem (B.)

For a morphism of \mathbb{E}_{∞} -ring spectra $\phi : R \to S$ and N an R-module, the set of isomorphism classes of descent data on $N \otimes_R S$ is equivalent to $\pi_0 \operatorname{Tot}(BAut(R/S^{\bullet}))$.

Remark

The Bousfield-Kan spectral sequence converges to the homotopy of the above totalization:

 $\pi^{s}\pi_{t} \Rightarrow \pi_{t-s} \operatorname{Tot}(BAut(R/S^{\bullet}))$

If our spaces are sets (e.g. 0-truncated) then π_{-1} of the totalization recovers the first nonabelian cohomology $H^1(R/S^{\bullet}; Aut(N))$.

Descent Cohomology & Twisted Forms in Homotopy

> Jonathan Beardsley

Classical Descent Theory

Twisted Forms and Descent Cohomology

Homotopical Descent (à la Lurie)

Sketch of proof:

- Aut(−) corresponds to taking based loops of R/S[•] with base point the canonical descent datum on N ⊗_R S (compare with Dwyer-Kan classification spaces).
- This forgets all other components and produces a cosimplicial loop space, which admits a delooping by a cosimplicial space.
- π₀ of this delooping is precisely the set of descent data
 on N ⊗_R S.

Remark

- If φ : R → S is a Galois (or Hopf-Galois) extension in the sense of Rognes, the above construction can be reinterpreted as homotopical Galois cohomology.
- In that case, a descent datum corresponds to an (co)action of a (Hopf-)Galois (algebra) group.
- The spectral sequence is a homotopy (co)fixed points spectral sequence.
- ► Tyler Lawson and David Gepner are doing computations along these lines for the Galois extensions KO → KU.
- Vesna Stojanoska and Akhil Mathew are also doing these kinds of computations for TMF → TMF(n).
